CareerNet – Sprint 2 Summary Report

1) **Sprint Objectives**

   Sprint 2 aimed to turn CareerNet from an authentication shell into a working job-seeker experience: profiles, job search, job details and application tracking, with the backend data model to support them. We also put engineering practices in place so the project can grow safely: automated tests, continuous integration and a protected main branch.

2) **Features and Functionality Implemented**

   Job seekers can manage a profile, upload and manage resumes, search and filter jobs, open a job's details, apply with a resume and an optional cover note, and follow each application's status on a My Applications page. Recruiters can post jobs, view the applicants for their own postings and update an applicant's status. On the backend, we added profile, resume, job and application tables with migrations, a sample-jobs seed script, and authenticated endpoints for profiles, resumes, jobs, applications, recruiter postings and status updates.

3) **Team Innovation and Original Features**

   CareerNet's distinguishing features are AI-generated resume feedback and job matching based on both a seeker's CV and their stated career goal, rather than keyword search alone. when a recruiter updates an applicant's status, the seeker sees it on their dashboard. Sprint 2 laid the groundwork for these: resume storage, structured job data with search, and the applications table with statuses. The AI features are planned for Sprint 3

4) **Challenges and Resolutions**

   Frontend screens were ready before their endpoints. We built them against mock data that follows our shared API cheat sheet, so switching to the real backend is a small change. Several branches edited the same routes and caused merge conflicts, which we resolved by merging main into each feature branch before review. Branch protection and a CI pipeline now block untested code from reaching main, and we demonstrated both a passing and a failing run.

5) **Team Contributions**

   Sayf: test setup, automated tests, CI pipeline, branch protection, applications table, sprint planning and coordination.

   Kaila: database models and migrations, sample-job seed script, resume and job search.

   Lamees: profile endpoints, resume and apply endpoints.

   Youssef: job and recruiter endpoints.

   Krish: profile page, job listing, search and filters, job detail, My Applications, resume upload, apply dialog and recruiter dashboard screens.

   Dany: mock data, job search and filter controls, job listing, shared API helper and sprint2 summary report.
